DNA is the molecule that stores the genetic information in your cells. That information is coded in the four **bases** of DNA: C (cytosine), G (guanine), A (adenine), and T (thymine). The DNA directs the functions of the cell on a daily basis and will also be used to pass on the genetic information to the next generation. Because of its critical role in all the functions of the cell, DNA is kept protected in the nucleus of your cells. DNA is organized in sections called **genes**. Genes code for **proteins**, and it is proteins that do all the work in the cell. They function as **structural proteins** — serving as the building blocks of cells and bodies. And they function as **enzymes** — directing all the chemical reactions in living organisms.

Proteins are made in the **cytoplasm** by **ribosomes**. Since DNA cannot leave the nucleus, the *information* from DNA must be transmitted from the nucleus to the cytoplasm. During **transcription**, each gene on the DNA is read and codes directly for a **messenger RNA (mRNA)** molecule. The mRNA is made by matching its complementary bases — C, G, A, and U (**uracil**) — to the DNA bases. This process is called *transcription*, because the message is going from one version of nucleic acid language (DNA code) to another version of nucleic acid language (RNA code), so it is like transcribing from the key of G to the key of C in music. Before leaving the nucleus, this primary mRNA transcript is modified in several ways. **Introns** (intervening non-coding units) are edited out and **exons** (expressed coding sequences) are spliced together. In addition, a 5' **GTP cap** and a 3' **poly-A tail** are added to the mRNA to protect it from RNase enzymes in the cytoplasm. This mature mRNA transcript then leaves the nucleus and carries the code for making the protein from the DNA gene in the nucleus to the ribosome in the cytoplasm.

During **translation**, the ribosome reads the sequence of bases on the mRNA in sets of three — the triplet **codons**. Another type of RNA — **transfer RNA (tRNA)** — brings the protein building blocks — **amino acids** — to the ribosome as they are needed. The ribosome bonds the amino acids together to build the protein coded for by the gene back in the nucleus. This process is called *translation*, because the message is going from nucleic acid language (DNA/RNA code) to the completely different amino acid language (protein code), so it is like translating from English to Chinese.

PROCEDURE

1. Obtain the paper with 4 sections of DNA. Cut the strips out along straight lines and tape them together to make a long one-sided DNA molecule. Each section is numbered. Lay them out on the desk from left (#1) to right (#4). See the diagram below. This will form one long strand of DNA and will serve as the **template strand** of our gene.

2. We are going to use this section of our DNA as a gene to be transcribed and then translated into a protein the cell needs. Remember it used to be part of a double-stranded DNA molecule. But it has already been unzipped and now will be used as the template to build mRNA, one base at a time. So first design an **RNA polymerase enzyme** to do this mRNA synthesis job.

3. You have also been supplied with mRNA nucleotides. Build an mRNA molecule, one base at a time, from this gene by transcribing your DNA template. Don't forget to only start transcribing downstream from the **TATA box promoter sequence**. As you are transcribing, tape this mRNA molecule along its length to simulate the
